**Problem Set #8**

Issued: 5 Mar 12  
Due: 14 Mar 12

1. *Pattern formation by lateral inhibition. Based on Collier et al., Journal of theoretical biology, 1996*

The Notch-Delta signaling pathway allows communication between neighboring cells during development. It has a critical role in the formation of 'fine-grained' patterns, generating distinct cell fates among groups of initially equivalent neighboring cells and sharply delineating neighboring regions in developing tissues. In this problem, we investigate the pattern-forming potential and temporal behavior of the Collier model through numerical simulation.

The dynamics of Notch ( $n_p$ ) and Delta ( $d_p$ ) for each individual cell  $p$  are governed by:

$$\begin{aligned} \dot{n}_p &= f(\bar{d}_p) - n_p \\ \dot{d}_p &= \nu(g(n_p) - d_p) \end{aligned}$$

where  $\bar{d}_p$  denotes the mean of the levels of Delta activity in the cells adjacent to cell  $p$ , and

$$f(x) = \frac{x^k}{a + x^k}, g(x) = \frac{1}{1 + bx^h}$$

Consider a two dimensional array of cells, where each cell is modeled by a square. The parameters for the simulation are  $a = 0.01, b = 100, \nu = 1, k = h = 2, .$  Simulate Notch-Delta dynamics for a  $15 \times 15$  array of cells, using initial conditions chosen randomly from a uniform distribution. Use the code provided in `NotchDeltaGui.m` to provide a visualization of your simulation. Color cells with high Notch activity (if Notch activity is  $\geq 0.995$ ) in red, and low Notch activity level in black. Provide an illustration of the steady state of your simulation.

2. *Scaling of morphogen gradients. Based on Ben-Zvi, Barkai, PNAS, 2010*

Consider the feedback "expansion-repression" model for morphogen gradient scaling in which the range of the morphogen gradient,  $[M]$  increases with the abundance of some diffusible molecule  $[E]$ , whose production, in turn, is repressed by morphogen signaling. The partial differential equations

$$\begin{aligned} \frac{d[M]}{dt} &= D_M \nabla^2 [M] - (1 + [E])^{-1} \alpha_M^1 [M] - (1 + [E])^{-1} \alpha_M^2 [M]^2 \\ \frac{d[E]}{dt} &= D_E \nabla^2 [E] - \alpha_E^1 [E] + \beta_E \frac{1}{1 + ([M]/T_{rep})^h} \end{aligned}$$

and boundary conditions:

$$D_M \nabla[M]_{x=0} = -\eta_M$$

$$D_M \nabla[M]_{x=L} = 0$$

$$D_E \nabla[E]_{x=0} = 0$$

$$D_E \nabla[E]_{x=L} = 0$$

represent the dynamics of morphogen/expander concentrations with respect to position and time.

- a) Implement the system above using the technique discussed in class. Use the parameters below in addition to  $L = 15$  grid points,  $h = 4$ , cell size  $100 \mu m$  and time at steady state  $5 \times 10^5$  sec.

Morphogen diffusion, $D_M$	$10 \mu m^2 \cdot sec^{-1}$
$E$ diffusion, $D_E$	$10^{-1} \mu m^2 \cdot sec^{-1}$
Morphogen linear degradation rate, $\alpha_M^1$	$10^{-5} sec^{-1}$
Morphogen quadratic degradation rate, $\alpha_M^2$	$1 \mu M^{-1} \cdot sec^{-1}$
$E$ degradation rate, $\alpha_E$	$10^{-4} sec^{-1}$
Morphogen flux from proximal pole, $\eta_M$	$1 \mu m \cdot \mu M \cdot sec^{-1}$
$E$ production rate, $\beta_E$	$10^{-3} \mu M \cdot sec^{-1}$
Threshold for $E$ repression, $T_{rep}$	$10^{-3} \mu M$

Figure 1: Parameters for problem 4

- b) Plot the dynamics of the expansion-repression mechanism at three different times: when the morphogen gradient is sharp, when the gradient expands, and at steady state, along with the threshold. Explain the dynamics of the system in the three situations.
- c) Consider two examples of morphogen gradients defined by the expansion-repression topology for a field of length  $L$ : one that does not scale, and one that does scale with respect to the steady state morphogen gradient from part a). Plot each example separately on a scale of relative length  $x/L$ , where  $x$  is the position vs. morphogen concentration in  $\mu M$ . (Hint: try changing  $L$  and/or the cell size).
- d) What is the condition on the diffusion of the expander allows for scaling of the gradient?
